

PIPVENV

Creating a new virtualenv

```
pipenv --python 3.6
```

Enter current virtualenv

```
pipenv shell
```

Install a new package from PyPI

```
pipenv install jinja2
```

Install all packages listed in Pipfile

```
pipenv install
```

PIPVENV KEY TERMS

PyPI *Python Package Index* - Site with free Python packages.

pipenv Tool for downloading packages from PyPI into a *virtualenv*

virtualenv An “environment” that stores downloaded Python packages - each project gets one

Pipfile Keeps a log of what you download with pipenv, so you or teammates can get set-up again

MODULES

A module is a file or directory which provides functions, classes, or variables that can be imported and used by other Python files. Syntax and dir structure:

```
# - main.py
# - module_name/
#   - __init__.py
#   - submod_a.py
#   - submodule_b.py
import module_name
from module_name import (
    submod_a,
    submodule_b,
)
from module_name.submod_a import (
    function_name,
    variable_name,
    ClassName,
)
```

OOP TERMINOLOGY

OOP Object Oriented Programming - a way of thinking and arranging data in programming that groups types of data (“properties”) with functions (“methods”) and calls the entire thing a “class”

Class also known as an object’s “type”, classes form “blueprints” for creating new object instances, defining methods and properties

Object instance A specific occurrence of a class. Creating one is called *instantiation* or *construction*.

Property Data stored by the class, can be accessed with a “.” character

Method A function defined in a class declaration that gets attached (“bound”) to the object instances, also accessed with “.”

Constructor A special method that is run when you instantiate a class

Extend Classes (the subclass) can *inherit* or *extend* another class (the base class) which effectively copies over the methods and properties

Overriding When a subclass replaces a base-class method we say it is overridden

Super Super is a keyword to allow subclasses to access an overridden method on a base class

Software architecture Summary of the design of a piece of software to facilitate collaboration within a team

Interface The outwardly facing methods and properties of a class

PYTHON CLASS SYNTAX

```
class User:
    def __init__(self, name):
        self.name = name
        self.logged_in = False

    def login(self):
        self.logged_in = True

class StudentUser(User):
    def login(self):
        super(self).login()
        self.attended = True

user = User('Jo')
felix = StudentUser('Felix')
```

JINJA TEMPLATES

variables

```
<h2>Hi {{ user.username }}!</h2>
```

if

```
{% if age > 17 %}
    <p>You may continue.</p>
{% else %}
    <p>Too young.</p>
{% endif %}
```

for

```
{% for post in blog_posts %}
    <h2>{{ post.title }}</h2>
{% endfor %}
```

include

```
<h2>User details</h2>
{% include "user_snippet.html" %}
```

filters

```
<p>Hi {{ name|upper }}</p>
```

extends & blocks

```
{% extends "base.html" %}
{% block title %}
    Replaces base.html's block
{% endblock %}
{% block main_content %}
    Replace main_content
{% endblock main_content %}
```

USING JINJA

```
from jinja2 import Template
```

```
template = Template("""
    <h1>hi {{ name }}!</h1>
""")
```

```
result = template.render(
    name="Joaquin",
)
print(result)
```

TEMPLATING KEY TERMS

Context A dict with *context variables* to be inserted or otherwise used in various places in a template

Template A string or file typically of HTML, containing “placeholder” spots for variable data to be inserted, and simple logic

Render When a template is executed with a context
