JINJA TEMPLATES

variables

```
if
    {% if age > 17 %}
        You may continue.
    {% else %}
        Too young.
    {% endif %}
```

My name is $\{\{ \text{ name } \}\} \le /p >$

for

```
{% for post in blog_posts %}
    <h2>{{ post.title }}</h2>
{% empty \( \hat{\chi} \)}
    No posts found!
{% endfor %}
```

filters

```
Hi {{ name | upper }}
```

include

```
<form>
{% include "form.html" %}
</form>
```

extends & blocks

```
{% extends "base.html" %}
{% block title %}
    This replaces base.html's
    title block
{% endblock %}
{% block main_content %}
    Body might go here
{% endblock main_content %}
```

Using Jinja

```
# TODO fix
from jinja2 import (
    Template, Context
ctx = Context({
    "name": "Eric Idle",
})
template = Template("""
    h1>hi {\{ name \}\}}!</h1>
result = template.render(ctx)
print(result)
```

PIPENV

Creating a new virtualenv

```
pipenv --python 3.6
```

Enter current virtualenv

pipenv shell

Install a new package from PyPI

```
pipenv install jinja2
```

Install all packages listed in Pipfile

pipenv install

Modules

A module is a file or directory which provides functions, classes, or variables that can be imported and used by other Python files. Syntax and dir structure:

```
# - main.py
 - module_name/
#
     - __init__.py
     - submod_a.py
    - submodule_b.py
import module_name
from module_name import (
    submod_a,
    submodule_b,
from module_name.submod_a import ( Software architecture High-level,
    function_name,
    variable_name,
    ClassName,
```

JINJA KEY TERMS

Context A dictionary representing a collection of context variables to be inserted or otherwise used in various places in a template

Template A string or file, often consisting of HTML, containing "placeholder" spots for variable data to be inserted, and sometimes simple logic

Render When a template is combined with a context to produce finished results

OOP TERMINOLOGY

- OOP Object Oriented Programming a way of thinking and arranging data in programming that groups types of data ("properties") with functions ("methods") and calls the entire thing a "class'
- Class also known as an object's "type", classes form blueprints for creating new object instances, defining methods and properties
- Object instance A specific occurrence of a class. Creating one is called instantiation or constructrion.
- Method A function defined in a class declaration that gets attached ("bound") to every class instance, and can be accessed with a . character
- **Property** Data stored by the class, can be accessed with a . character
- **Constructor** A special method that is run when you instantiate a class
- **Extend** Classes (the subclass) can inherit or extend another class (the base class) which effectively copies over all the methods and property defaults
- Overriding When a subclass replaces a base class method we say it is overridden
- **Super** Super is a keyword to allow subclasses to access an overridden method on a base class
- executive summary of the design of a piece of software to facilitate collaboration within a team
- **Interface** The outwardly facing methods and properties of a class

Python Class Syntax

```
class User:
    def __init__(self, name):
        self.name = name
        self.logged_in = False
    def login(self):
        self.logged_in = True
class StudentUser(User):
    def login(self):
```

```
super(self).login()
self.attended = True
```
